

Microgrid load changes

Overview

This study introduces a Learning-based Load Frequency Control (LB-LFC) approach to manage the challenges posed by renewable energy's intermittency in microgrids, which often causes load disturbances, frequency fluctuations, and higher generation costs. Microgrids, particularly dynamic networked microgrids (DNMGs), offer a promising solution to mitigate the impacts of such contingencies and enhance resiliency. To prioritize power supply for critical loads and improve microgrid energy management efficiency simultaneously, this study proposes a method. The combination of microgrids and load shifting creates stacked economic benefits and, in some cases, may create synergistic value in which “the whole is greater than the sum of its parts.” These behaviors were explored and contrasted for three building types—apartment complex, hospital.
